ABSTRACT

Poultry meat is very popular in Ireland because of low cholesterol level. Ireland is in the top position for the consumption of poultry meat in whole Europe. Ireland emits 3.3 kg CO2-equivalent per kg of poultry for the poultry meat production which is the lowest amount among all the other European countries. To expand this sector with respect to environmental concern some issues need to be considered very carefully such as effective poultry feed production system, energy consumption in both poultry production and processing area, manure management system, wastewater and odour management systems. If these issues are not handled carefully, several types of harmful effects will occur in both living and environment cycle such as water borne diseases, global warming and ozone layer depletion. The objective of this report is to give an overview of the current situation of poultry production in Ireland, policies and legislation related to poultry production and to show the way to expand this sector in Ireland in line with current ecological concern.

Keywords: Ecological and policy, Management of poultry-waste, Poultry and environment, Poultry production

INTRODUCTION

Recently the department of agriculture, food and the marine announced that about 24 billion euro comes from agri-food sector in Ireland, and in the national economy, 6.3% gross value added, 10% of Ireland’s total exports and 7.7% of total national employment are contributed by this sector (Teagasc, 2012). By exporting chicken in 2014 Ireland earned 310 million euro and in 2015 the earning increased to 320 million euro (Bia, 2016). The Irish poultry industry is a very important contributor to the agriculture and economies of Ireland. This industry is growing very fast. The annual consumption of poultry meat has been almost doubled between 1980 and 2000 (FAO, 2009). In the European Union, Ireland was the highest position in per capita consumption of poultry meat (McCarthy et al., 2004).

The poultry industries were contributing a lot to meet the increasing need for the cheapest and safe supply of meat and eggs since last decade (Kearney, 2010). Many new changes happened in this growing sector such as structural changes, land independent farming, intense productions etc. The main intention was to decrease the production cost and increasing supply which have been done by improving animal genetics, optimized nutrition, efficient operations and new integrated technologies (Paul, 2010). All these things have given rise to environmental concerns. This is now not only limited to production area but also amplify to environmental problems at local and global scales. Globally greenhouse gas emissions are one of the main problems in the world. The emission sources can be categorized as i) feed production, using for fertilizers to produce feed and even production processes of that fertilizer, ii) on-farm energy consumption, iii) energy consumption for transporting poultry or poultry feed, iv) emission from manure management system, v) energy consumption in poultry processing area, vi) emission from waste or by-product of poultry processing. Mainly six gases are responsible for greenhouse gases. They are CO₂, CH₄, N₂O, hydrofluorocarbon, perfluorocarbon and sulphur hexafluoride (IOPC, 2007).
The emission of first three (carbon-dioxide, methane, nitrous oxide) are higher for faecal matter and the concentrations depend on the ventilation efficiency and rate (JRC, 2010). In Ireland, the carbon footprint of poultry and egg production is low compared to other European countries. But from the ecological point of view in growing and to expand the poultry sector in Ireland utmost concern should be given at this field. In this review, current situation of poultry production along with European and Irish policies and legislation, carbon footprint, environmental issues and the prevention of the poultry waste with the expansion of this sector are discussed.

**Poultry production in Ireland**

In Ireland, four systems are maintained for poultry production. Those are intensive (commercial), free-range, label rouge and organic. Main differences between these production systems are shown in table 2 (Lampkin, 1997).

Intensive production is a very common and commercial process. In this process, chickens are raised up in a controlled environment and high nutrient feeding system. Breast meat is very popular in Ireland. That is why breeders are preferred which give a high amount of breast meat. Normally it takes 35 to 56 days to reach the weight 3kg of chicken and in case of intensive egg production around 290 eggs can be collected per chicken per layer cycle.

Free range is also a popular system where chickens are allowed access to the outdoors. These birds take around 56 days to grow up. According to Teagasc (2006a) there are some regulations for free-range farming in Ireland. Those are i) chickens should be allowed daytime access for open-air running, ii) the ground should be covered with plant or grass, iii) the maximum stocking density has to be a thousand chickens per hectare, iv) an insulated house has to be made with a floor space of one-meter square per seven chickens (Teagasc, 2006a).

Label Rouge is a French pasture-based production arrangement. According to this system, there is some regulation for using feeding ingredients such as diets should contain 65% cereal. At six weeks age a ring is worn on the pullet’s wing by the certifying organization. The density has to be 13 pullets per m<sup>2</sup>. Normally chicken lays after 21 weeks when it will go through a complete light and nutrition program.

Organic table birds and layers are very popular in whole Europe. It must be maintained by the European council regulations and examined by certifying bodies of each country. In Ireland, there are three organic certification constitutions.

1. Demeter standards
2. Irish organic farmers and growers association
3. Organic trust (Teagasc, 2006b)

Around 29850 ha agricultural land was used for organic food in 2002 in (DAF, 2002). Most of the organic foods in Ireland are fruits and vegetables. Organic meat mainly beefs and lambs are occupied 25% of the organic food. Organic poultry and egg are negligible due to the limited supply (DAF, 2002). Table 1 shows the total number of producers and birds involved in organic poultry production in Ireland in 2002.
The market for organic poultry feed is very small. Hence only one supplier is available all over Ireland (Teagasc, 2006b). This feed is very expensive almost 80% expensive than normal poultry feed. This feed must be free from any types of genetically modified organisms. Chickens which are produced for organic meat production requires 81 days to grow up which is a lengthy procedure (Teagasc, 2006b).

### European and Irish policies and legislation

In Europe union, the poultry meat production is directed by the European communities (fresh poultry meat) regulations 1996 (S.I. No. 3/1996) and council directive 71/118/EEC European Economic Community (EEC) (Directive, 1996). This regulation controls the premises approval, application of the health mark to poultry, hygiene and sanitary standard etc. European communities (marketing standards for poultry meat) regulations 2002 (S.I. No 440) cover the marketing standards such as labelling, grading by quality etc. (Magdelaine et al. 2008).

The Poultry hatcheries act 1947 and the poultry hatcheries regulations, 1959 controls about the breeding stock as they should be collected from permitted breeding sources. It also controls the inspection and blood testing to keep poultry free from diseases (HARRIS, 1973).

European communities (marketing standards for eggs) regulations, 254/1992 implementing regulation (EEC, No. 1907/90) and regulation (EEC, No. 1274/91) deals with egg grading, weighing, packing, labelling, transporting and marketing. The egg for incubation is not allowed for human consumption (EISB, 1992b).

According to Ireland rules and regulation, if anybody is going to deal or trade poultry for commercial or non-commercial basis has to be certified with the department of agriculture, fisheries and food under the diseases of animals act 1966 (registration of poultry premises) order 2008 (S.I. No. 42 of 2008 as amended by S.I. No. 57 of 2011). And that person must be committed to the rules of biosecurity and record keeping requisites (DAFM, 2013)

The regulation for poultry manure is written in statutory instruments S.I. No. 378 of 2006. All the requirements are written here for that person who will apply for Integrated Pollution Prevention and Control (IPPC) license. The Environment Protection Act, 1992 is required for the following activities (EISB, 1992a).

1. Any type of emission cannot violate the air quality standard enumerated under section 50 of air pollution act, 1987.
2. Any type of emission cannot violate the quality standard of waters, trade effluents and sewage which is enumerated under section 26 of the local government (water pollution) act, 1977.
3. Any type of emission from the action of plant, methods or procedure cannot violate the rules of European communities act, 1972.
4. Any noise cannot violate the rule under section 106.

Environmental protection agency act 1992 (established activities) order, S.I. No. 279 of 2006 deals with poultry installation in Ireland (Intertradeireland, 2011). The key legislative concerned to poultry production in Ireland is actually characterized by the following standards:

1. International quality management standards as for example ISO 9001:2000
2. Hazard analysis and critical control points as summarized by Codex Alimentarius (1997)
4. EN 45001 (1998) general requirements of bodies who are involved in product certification systems (Bord Bia, 2008).

### Carbon footprint during poultry production

According to food and agriculture organization report “livestock long shadow: environmental issues and options” livestock production is one of the main issues for the environment. The report showed that around 18% Greenhouse Gas (GHG) emissions come from livestock (FAO, 2006). GHG is lower in pork and poultry for the adequate digestion process and inexistence of enteric fermentation process. And the GHG emission is lower in poultry comparing to pork. In the European Union considering product level 19 to 28kg CO2-equiv. per kg of meat (beef, sheep and goat) is the total GHG intensity. Comparing that amount poultry gives only 5-7kg CO2-equiv. which is less. The emission of CH4 and NO is high
for poultry production. Egg considerably gives lower carbon footprint. In Europe, union egg production causes a net emission of 2.8–3.2 kg of CO2-equiv. per kg of eggs. In Ireland, poultry meat production emits 3.3 kg CO2-equiv. per kg of poultry (Weiss and Leip, 2012).

Jacob (2009) showed the average GHG emission in a broiler industry. He stated that 5.5 tons CO2 emission happens for 1000 broilers marketed, 7.5 lbs CH4 emission occurs per thousand broilers marketed and 3.8 lbs N2O emission occur for thousand broilers marketed.

The carbon footprint of Ireland in the livestock sector is always lower than any other country in Europe union. Joint research center of the European Union commission published major research in which Ireland is rated amongst the best for the carbon footprint (Teagasc, 2011). The research entitled “evaluation of the livestock sector contribution to the Europe Union GHG emissions” demonstrated the carbon emission of livestock products, the production of feeds. It also reported the emission due to an input of mineral fertilizer, pesticides, energy etc. from this study, the poultry carbon footprint was 3.3 kg CO2-eq per kg of poultry where the average value of carbon footprint in European Union is 4.9 kg CO2-eq per kg of poultry (Teagasc, 2011).

From figure 1, it can be easily noticed that among the other European countries the emission of GHG in Ireland for egg production is really low. It is near about 2.5 kg CO2-equiv. per kg of product. From figure 2, it also can be easily noticed that the position of Ireland for poultry meat production is really not the alarming phase. Ireland is in the lowest position for the emission of GHG in case of poultry meat production.
Environmental Issues

In a poultry processing area, some factors are very important to control environmental hygiene. The factors are exterior structure and grounds, interior structure, interior walls, ceiling and overheads, floors, drainage, doors, windows, lighting, water and water supply, knives, sterilizers, hoses and other equipment, extraction and ventilation, cleaning materials and storage, food trays, electronic fly killers, effluent treatment and complete waste disposal system (FAO, 1996).

Mainly two important parts are important for ecological aspects. One is the production of concentrated feed and another is the generation of GHG through chicken processing and transporting of processed product.

Environmental impacts of poultry feed production

The feeds for poultry consist of main cereals, soy, oilseeds and pulses. Intensive feed production effects negatively to the land and water. To produce high crop yield mineral fertilizer, pesticides and different herbicides has to be used intensively which pollute the environment. Smil (1999) reported that 30-50% of nitrogen fertilizer and 45% of phosphorus fertilizer is absorbed by the plant. For feed production in the world, about 20 million tons of nitrogen fertilizer is used and 36% of that feed is produced as poultry feed. This also causes serious air pollution because of the volatile nature of ammonia. Feed production also affects negatively in biodiversity. The increasing demand for feed requires expansion of cropland and thus it affects through the adaptation of natural habitats. Sometime overexploitation of fisheries is happening for producing the fishmeal for the poultry (Steinfeld et al., 2007).

Environmental impacts on poultry manure

The growing poultry industries are giving serious concern about poultry waste mainly poultry manure. Poultry litter is a very good origin of organic fertilizer. But this poultry manure creates some environmental problems such as nitrite that extracted into the groundwater, phosphorus from poultry manure mixes up with surface water bodies and various pathogenic organism released by poultry manure. The most important thing to the poultry manure management system is to keep the manure dry as early as possible (Moore et al., 1995).

Environmental impacts on air quality

In chicken production houses three gases are of greatest concern. Those are ammonia, carbon dioxide and carbon monoxide. Table 3 revealed that both long and short term CO₂ produce significantly had high amount than ammonia and Carbon monoxide. These gases negatively impact on human health.

Personnel-related to poultry production systems have to be aware of the location and production so that the air emission does not hamper the local environment. To establish a new production, house a producer can reduce problems related to the environment in many ways such as proper ventilation system, cover poultry litter, the proper management system of wastewater and waste packaging material, transporting through proper vehicle etc. Producers and processor should be careful because if they cross the limit they will need EPA license.

Prevention of poultry waste production

Industrial poultry waste management; in the poultry processing industry, various waste products are produced which have to be managed or processed for the safety of the environment. Some common practices are discussed here:

In a modern plant, flow-away systems are being used for fast and adequate processing. To reduce blood loss before killing stunning should be done. If stunning is not done blood may be spattered over a large area and deteriorate feathers. Dry cleaning is important before washing the whole receiving area. Feathers which are recovered can be disposed of or cooked by pressure to hydrolyze the keratin protein. Screened water should be used in the de-feathering operation. Feet, head, viscera and other parts which are inedible should be gathered for disposal or inedible analysis. Final evisceration wash water can be re-used for other unimportant sub-processes. The special nozzle should be used to reduce the wastage of water (FAO, 1996).

Wastewater management

Wastewater from the poultry processing industry causes a serious environmental impact. It mainly hampers the natural environment in three ways. The waste water contains a lot of biodegradable compounds which reduce the dissolved oxygen in the water. Water containing...
reduced dissolved oxygen is very harmful to aquatic life. Eutrophication may occur due to the presence of macro-nutrients such as nitrogen, phosphorus in the water bodies. Excess algae growth and their consecutive dying release too much mineral in water which also affects harmfully to the aquatic life. Some effluent compounds directly harm aquatic life such as un-ionized ammonia (Demayo et al., 1982). In the poultry processing industry, the offal flume water contains one-third of the total waste load. It has been reported that the average value of biological oxygen demand (BOD) is 3.4 kg per ton of LWK (live weight killed). The highest BOD is found in chicken blood around 4.5 kg BOD per ton of LWK. The detailed values are showed in table 4.

Scalding is the processing step in which maximum energy consumption takes place. The scalding tank which contains residues and feathers holds 0.6 to 3.1 kg BOD per ton of LWK. In the chilling process, the overflow water contains 0.4 to 2.5 kg BOD per ton of LWK. Final wash water holds 0.7 kg BOD per ton of LWK. About half of the BOD comes from cleaning operation in a poultry processing industry (FAO, 1996).

### Manure management

Statutory Instruments S.I. No. 378 of 2006 deals with poultry manure management. The litter from the poultry farm should be stored in the litter storage shed. That shade should have 347-meter square floor area. Shed also contains a ditch for wash-waster holding. That ditch should be the 8.1-meter cube. Normally 1-meter cube space is needed for 600 kg of litter. A contractor will provide all the necessary things like machinery or labor to clean the houses and transfer the litter to the storage shed (EPA, 2009).

### Emissions minimization

Emission to air, water or land that occurred for poultry housing can be prevented or minimized in many ways. Walls and roofs in the poultry house should be properly insulated and smooth enough for cleaning easily. The building should be waterproof. Forced air drying system should be used to dry manure rapidly on belts. This drying and stabilization will reduce flies. Gable fan and air inlet should be conducted electronically. Gable fan will be only operated when the temperature will rise more than 25 °C. Fans should be adapted with light filters to minimize emissions. Fans should be cleaned on a regular basis. Nipple drinker system should be used to minimize water wastage and to manage dry manure to reduce the emission of ammonia. Low energy lighting should be used. A review of housing and overall management should be carried out after 12 months and after following that review developed method should be implemented for the next year.

Manure should be dried instantly within 24 hours for volatilization of ammonia. Dried manure should be sent to manure store (Alberta, 2008).

### Energy minimization

The artificial heating system is not commonly adapted for the layer farms because of high stocking density and low temperature. Common activities regarding energy requirement are heating the water in the winter season, distributing system of feed, ventilating the house, lighting (high energy consumption requires here), collecting and sorting of eggs and packaging. On the other way, in a broiler farm energy requires for the heating system which is being done initial phase, preparing and distributing of feed and ventilating of the house which is weather dependent.

To reduce the energy consumption for poultry production some methods can be applied, such as high-quality insulation in walls and roof, automatically ventilation and constant temperature controlled systems. On the other hand, in the feeding system, power consumption can be increased if high friction occurs. So effective and automated feeding system installation is necessary to minimize the energy consumption (Baxevanou et al., 2017).
Effective measures to monitor emissions

Emissions to air
Sometime incinerator should be used to burn carcass. Small incinerator (less than 50 kg per hour) should be used. The temperature inside the incinerator should reach to 85 °C for complete combustion. Monthly checking is necessary for the incinerator.

Emission to water
The dry cleaning system is used which remove completely the contaminated run-off. Sometimes it is passed directly from hard standing region to waste water tank. According to the code of good practice, the wastewater tank should be emptied to thoroughly clean up. Record keeping should be done with checking or emptying of the tank (Sparrey, 1994).

Emission to land
Discharging of ammonia and dust from the air and spreading manure on soil may be the reasons for emissions to land (Sharp, 2006).

Odour minimization
The odour of poultry waste may be minimized by taking some steps. Effective dry manure system is maintained with controlling humidity, temperature and prevent leakage at the water supply system. High standard of cleanliness should be maintained by regularly cleaning up deposited dust, the dead body removes and controlling internal weather condition. For preventing feed wastage storage bins should be sealed (Ranadheera et al., 2017).

CONCLUSION
Ireland is the highest position for consuming poultry meat among other European countries and on the other hand, this country has the lowest position for emission of greenhouse gases for poultry meat production. Here chicken meat production emits 3.3 kg CO₂-equiv. per kg of poultry. So the situation is not critical yet. But it is going to be critical soon if the necessary preventive measure will not be taken in the near future. Consumption of poultry meat is increasing daily. The new technologies are being used which consequently increase GHG. Intensive poultry production is popular here which gives fewer GHG compared to free-range poultry production. Through maintaining the rules and legislation for poultry farming in Ireland, it is very much possible for the poultry farmers to expand their business. Not only the poultry production industries but also the poultry processing industries need to be concern about ecological aspects. They produce the largest amount of BOD in the whole processing systems. Effective poultry feed production, energy consumption in both poultry production and processing area, manure management system, wastewater and odour management system all these are very importantly handled as these systems are directly affiliated to the environment. Proper knowledge on the current scenario of poultry production in Ireland with ecological concern and the proper guidance with European and Irish policies and legislation are the basic need to expand this sector.
