ABSTRACT

*Bacillus cereus* is an opportunistic pathogen that can cause food poisoning in humans as a result of consuming foods containing toxins or bacteria. In this study, the incidence of *B. cereus* and its virulence genes in meat products was investigated. Isolation of *B. cereus* was performed using selective PEMBA media and confirmed by morphological and biochemical tests and Vitek2 compact system. The incidence of *B. cereus* strains in beef and chicken meat products was 28%. The incidence of *Bacillus cereus* in frozen rice kofta, frozen kobiba-shami, chicken pane, and chicken nuggets was 16%, 24%, 28%, and 44%, respectively. Moreover, the result of multiplex PCR of virulence genes of *groEL* gene (533bp), *Hbl* gene (1091 bp), *Nhe* gene (766 bp) and *CytK* gene (421bp) indicated that *groEL* gene, *Nhe* gene, *CytK* gene was found in 100% of *B. cereus* isolated from different meat products, while *Hbl* gene was detected in 10% of isolates. The results demonstrate that meat products represent a threat to public health through the transmission of *Bacillus cereus*.

**Key words:** *Bacillus cereus*, Beef meat, Chicken meat, PCR, Virulence genes, VITEK2

INTRODUCTION

The genus *Bacillus* includes harmless environmental and pathogenic species. The *B. cereus* group is known as pathogens or opportunistic pathogens to humans (Logan, 2012). The *B. cereus* is associated with food poisoning as a result of the consumption of food containing pre-formed toxins or bacteria producing toxins in the human gut (McKillip, 2000).

Genus *Bacillus* are Gram-positive rods able to produce endospores resistant to unfavorable external conditions (Logan and Devos, 2009) that can be distinguished from other spore-formers (*Sporolactobacillus, Clostridium, Desulfotomaculum, Sporosarcina, and Thermoactinomyces*) due to their aerobic character (strict or facultative), rod-shaped cells and catalase production (Slepcky and Hemphill, 2006). Schedule identification of *B. cereus* is generally combined with isolation on selective media, illuminating of motilility, hemolysis pattern on blood agar, and acidification of glucose (Stenfors et al., 2008).

The pathogenesis of *B. cereus*-induced food poisoning is mostly still unclear. The microorganism transmits an expansive number of potentially toxic components, including hemolysins, phospholipases, and proteases (Beecher, 2001) nevertheless, the accurate role of some toxins is still unclear. The emetic and the diarrheal syndromes are still the foremost concerns for the public health apprehension and the full appreciative of their pathogenesis is imperative. These syndromes are mainly revealed via the release of two core toxins, a heat-labile diarrheal enterotoxin, and heat-stable emetic enterotoxin (Stenfors et al., 2008).

The diarrheal syndrome revealed via the release of one or three diarrheal enterotoxins: the tripartite toxins hemolysin BL (*HBL*) and non-hemolytic enterotoxin (*Nhe*), the two forms of cytotoxin K (*cytK*-1 and *cytK*-2) and possibly enterotoxin T and enterotoxin FM (Moravek et al., 2006). *HBL* is a three-component toxin, that is encoded by *hblD* and *hblC* genes respectively, and a binding component B encoded by *hblA* gene. The presence of all three components is important for the activity of toxin (Lindback and Granum, 2006).

The objective of this study was to conduct bacteriological and molecular studies on *B. cereus* isolated from frozen rice kofta, frozen kobiba-shami, chicken pane, and chicken nuggets.
MATERIALS AND METHODS

Collection of Samples
A total of one hundred random samples of meat products which including frozen rice kofta, frozen kobiba-shami, chicken pane and chicken nuggets (25 of each) were collected from different shops, supermarkets in different localities in Menoufia and Kalyobia governorates. Samples conveyed to the laboratory following aseptic and safety precautions.

Isolation and identification of Bacillus cereus group
A stomacher was used to homogenize 10 g of each sample in 90 mL of buffered peptone water (BPW) for 2 min. Heat treatment of all samples at 70 °C for 15 min was used to eliminate vegetative cells and allow the isolation of spores (Al-Allaf, 2011). The pasteurized samples were immediately positioned in ice to prevent spore germination. An amount of 100 μl was spread on Polymyxin-pyruvate-Egg yolk-Mannitol-Bromothymol blue agar (PEMBA) media plates and incubated at 37 °C for 24-8 hr both aerobically and anaerobically. The plates were examined and the presumptive B. cereus group was confirmed based on microscopy of Gram-stained preparations and biochemical tests (FDA, 2015). A number of colonies were randomly collected and analyzed by cell morphology under the microscope, Gram staining, ability to form endospores, growth in the presence of sodium chloride, anaerobic growth, catalase and oxidase activity, Voges-Proskauer test and growth at pH 5.7. The ability to ferment carbohydrates, starch hydrolysis, use of citrate as a carbon source, lecithinase activity, and growth inhibition by lysozyme were applied (Al-Allaf, 2011 and FDA, 2015).

Identification of Bacillus cereus using VITEK2 BCL Card
Bacterial suspensions were arranged in 3.0 mL of sterile saline and accustomed to a McFarland standard of 1.80-2.20 using the VITEK2 DensiChek (bioMe‘rieux). BCL cards were packed automatically in the VITEK vacuum chamber, sealed, incubated at 35.5°C and read automatically every 15 min for 14 hours. Data were investigated automatically using the VITEK2 database.

PCR detection of virulence Bacillus cereus isolates DNA extraction
The isolates of B. cereus isolates from different meat products were grown in 5 mL nutrient broth with shaking for 18 h at 30 °C and collected at 5,000 g for 5 min. QIAamp DNA Mini Kit was used for genomic DNA extraction and purification. PCR was achieved to detect groEl gene and three enterotoxigenic encoding endotoxins genes Nhe, hbl and cytK genes. A positive reference strain of B. cereus ATCC 14579 and sterile MilliQ water as a negative control was used in PCR analysis (Ehling-Schulz et al., 2006; Das et al., 2013). Table 1 provides details about the primers used.

Preparation of PCR master mix
occurred according to Emerald Amp GT PCR mastermi (Takara) CodeNo.RR310A kit as shown in table 2.

Cycling conditions of the primers during PCR
PCR conditions are shown in table 3. Gel electrophoresis was used to analyze PCR fragments for presence and correct size compared to positive control (Sambrook et al., 1989). PCR runs where a negative control displayed amplification or positive control did not amplify were overlooked and repeated.

RESULTS

Prevalence of Bacillus cereus in meat products
The prevalence of B. cereus in meat products (frozen rice kofta, frozen kobiba-shami, chicken pane, and chicken nuggets) was 16%, 24%, 44%, and 28%, respectively. Out of 28 Bacillus isolates, 18 (36%) isolates obtained from chicken product samples and 10 (20%) isolates were recovered from beef product samples. The incidence of B. cereus group in the different meat products shown in table 4.

PCR results
The result obtained using agarose gel electrophoresis of multiplex PCR of virulence genes, groEL gene (533bp), Hbl gene (1091 bp), Nhe (766 bp) and CytK gene (421bp) for characterization of virulence genes of B. cereus isolated from different meat products showed that groEL gene (Figure 1), Nhe gene (Figure 3) and CytK gene (Figure 4) were found in 100% of tested isolates of B. cereus and the Hbl gene was detected in 10% of tested B. cereus isolates (Figure 4).

DISCUSSION

Food-borne diseases are reported to be a serious hazard to public health all over the world. Among the organisms responsible for causing foodborne diseases, *B. cereus* has emerged as a major foodborne pathogen during the last few decades and causes two types of illness through the elaboration of enterotoxins (Jay, 2005).

In this study, the incidence of *B. cereus* in meat products was 28%. These results were nearly similar to that obtained by Tewari et al. (2015), who isolated *B. cereus* from 35% of meat products. The results of the present study were higher than those obtained by Ashraf et al. (2019), who isolated *B. cereus* at a percentage of 11.24, while the results were lower than those obtained by Shimaa et al. (2018) who isolated *B. cereus* at a percentage of 47%.

The incidence of *B. cereus* in beef meat products was 20% that was lower than that obtained by Hesham et al. (2018), where the incidence of *B. cereus* was 38.2%. The incidence of *B. cereus* in chicken meat products was 36% nearly similar to results obtained by Hesham et al. (2018), who isolated *B. cereus* from chicken meat products at a rate of 48%.

The incidence of *B. cereus* in Kobeba-shami was 24%. This result was lower than that obtained by Shimaa et al. (2018) where the incidence of *B. cereus* was 52% and Hemmat et al. (2014) who isolated *B. cereus* from 84% of the examined kobeba-shami samples. The incidence of *B. cereus* in Rice kofta was 16%. This result was lower than that obtained by Shimaa et al. (2018) who isolated *B. cereus* at a rate of 60%. The incidence of *B. cereus* in nuggets was 28%. This result was lower than that obtained by Smith et al. (2004) who isolated *B. cereus* at a percentage of 91.6%. The incidence of *B. cereus* in chicken pane was 44% that was higher than that obtained by Smith et al. (2004) who failed to isolate *B. cereus* from examined chicken products.

These variations in the results were attributed to the quality of raw materials and the hygienic state during the preparation and processing of the product. The high frequency of isolation of *B. cereus* from meat products may be attributed to the processing of minced meat also additives and spices added to these products, which can increase the number of *Bacillus* spores. Therefore it is important to use additives from a trustful source during the processing of raw meat and test these additives regularly for the presence of *Bacillus* spore (Shawish and Tarabees, 2017). VITEK2 BCL Card is a highly advanced method for the identification of *B. cereus* (Halket et al., 2010).

In this study, 100% of tested *B. cereus* isolates harbored Nhe gene that this result is in accordance with that presented by Anderson et al. (2001) and Ashraf et al. (2019), while Hbl gene was found in 10% of the tested isolates, which is similar to findings reported by Ashraf et al. (2019). Also, 100% of tested *B. cereus* were found to harbor cytK gene and this result approved with Kamelia et al. (2018) (81.5%) and Ngamwongsatit et al. (2008). Also, groEl gene was present in 100% of tested *B. cereus* which is a valuable target for phylogenetic studies to detect the *B. cereus* (Chang et al., 2003) and has already been used in PCR assay to detect the *B. cereus* (Taylor et al., 2005; Chang et al., 2003).
